

Homework 6

APPM 5650 Fall 2021

Randomized Algorithms

Due date: Monday, Oct 4 2021

Theme: Reading and sampling

Instructor: Prof. Becker

Instructions Collaboration with your fellow students is allowed and in fact recommended, although direct copying is not allowed. Please write down the names of the students that you worked with. The internet is allowed for basic tasks only, not for directly looking for solutions.

An arbitrary subset of these questions will be graded.

Problem 1: [READING] Read sections 1 (“Overview”) and 2 (“Related Work and Historical Context”) from “Finding structure with randomness: Stochastic algorithms for constructing approximate matrix decompositions” by Halko, Martinsson and Tropp (SIAM Review 2011) available at <http://users.cms.caltech.edu/~jtropp/papers/HMT11-Finding-Structure-SIREV.pdf>

Deliverable: Write at least 1 paragraph about your response to the reading, e.g., what did you find interesting? Or, according to the authors, when did randomized methods start to have an impact on numerical linear algebra? What do the authors claim is responsible for some of the resistance in adopting randomized techniques?

Problem 2: [MATH] Sampling schemes. We would like to sample roughly k items out of n . We’ll consider only sampling without replacement schemes for this problem, so our samples Ω can be written as a set (we don’t need an ordered list). We’ll consider two models:

- SRS (simple random sample, without replacement) which is uniformly sampling all possible subsets of size k . We write $\mathbb{P}_{\text{SRS}(k)}[\cdot]$ to denote sampling under this model. The sampled set Ω is always of size k .
- Bernoulli sampling with rate $\rho \approx k/n$. Each entry of $[n]$ is included in Ω with probability ρ , all done independently of the other entries, so $\mathbb{E}[|\Omega|] = \rho n \approx k$. We write $\mathbb{P}_{\text{Ber}(\rho)}[\cdot]$ to denote sampling under this model.

We consider some randomized algorithm, and we wish for it to be successful (meaning, say, that the error is below some given threshold). We let **success** be the event that the algorithm is successful. Our main assumption is that more samples in Ω is better: specifically, that

$$\mathbb{P}_{\text{SRS}(k)}[\text{success}] \leq \mathbb{P}_{\text{SRS}(k')}[\text{success}] \quad \text{if } k \leq k' \quad (\text{Assumption})$$

We’ll show that if we can control the probability of success under the Bernoulli scheme, then we can also control it under the SRS scheme (hence we could analyze the Bernoulli scheme but do the SRS scheme in practice and still have similar guarantees). Specifically, let Ω be a sampled set drawn under the Bernoulli scheme with parameter ρ , and do the following:

- Explain why $\mathbb{P}_{\text{Ber}(\rho)}[\text{success} \mid |\Omega| = k] = \mathbb{P}_{\text{SRS}(k)}[\text{success}]$
- Under (**Assumption**), show that

$$\mathbb{P}_{\text{SRS}(k)}[\text{success}] \geq \mathbb{P}_{\text{Ber}(\rho)}[\text{success}] - \mathbb{P}_{\text{Ber}(\rho)}[|\Omega| < k].$$

Hint: use the Law of Total Probability, conditioning on the size of Ω .

- c) For any $\delta > 0$, set $\epsilon = \sqrt{\frac{\ln(\delta^{-1})}{2n}}$ and set $\rho = k/n + \epsilon$, so we expect Ω to have size $k + \epsilon n$. Show $\mathbb{P}_{\text{SRS}(k)}[\text{success}] \geq \mathbb{P}_{\text{Ber}(\rho)}[\text{success}] - \delta$. *Hint:* use a concentration inequality.

[NO WORK NECESSARY] Note that similar arguments can also be used to show that $\mathbb{P}_{\text{Ber}(\rho)}[\text{success}] \geq \mathbb{P}_{\text{SRS}(k)}[\text{success}](1 - \delta)$ for $k = n\rho - \epsilon$ for a similar ϵ to the previous problem, meaning that if you analyzed SRS sampling but wanted to do Bernoulli sampling in practice, you also get guarantees.

This problem follows the Appendix in *Robust Principal Component Analysis?* by Candès, Li, Ma and Wright 2009 (but don't look *before* attempting the above problems).
